a Group-level CCA: where chance alone gives large correlations

mean first canonical correlation under no association, simulated as in Section 6.1 (M = 21, size weights)

b The annotation ratio decides what can be detected

null distribution of the group-level R^2 of any score on the annotations

At κ near 1, a group-level fit explains almost all between-group variance of any score. With size weights and unequal sizes the null mean exceeds κ (dots, mean of 1,000 data sets): the large groups dominate both the score and the annotations.
